Nano-Cutting Fluid for Enhancement of Metal Cutting Performance

S. KHANDEKAR, M. RAVI SANKAR, V. AGNIHOTRI, AND J. RAMKUMAR

Department of Mechanical Engineering, Indian Institute of Technology, Kanpur, India

Nano-cutting fluids are the mixtures of conventional cutting fluid and nanoparticles. Addition of the nanoparticles can alter wettability, lubricating properties, and convective heat transfer coefficient (cooling properties) of nano-cutting fluids. In the present work, nano-cutting fluid is made by adding 1% Al_2O_3 nanoparticles to conventional cutting fluid. The wettability characteristic of this nano-cutting fluid on a carbide tool tip is measured using the macroscopic contact angle method. Comparative study of tool wear, cutting force, workpiece surface roughness, and chip thickness among dry machining, machining with conventional cutting fluid as well as nano-cutting fluid has been undertaken. This study clearly reveals that the cutting force, workpiece surface roughness, tool wear, and chip thickness are reduced by the using nano-cutting fluid compared to dry machining and machining with conventional cutting fluid.

Keywords Chips; Force; Morphology; Roughness; Wear; Wettability.

INTRODUCTION

The most desirable properties of cutting fluids are cooling (superior convective and conductive heat transfer coefficient), lubrication, and evacuation of chips from machining zone. Cooling is one of the most important challenges in the machining process faced by numerous industries such as automobiles, electronics, and manufacturing [1–5]. New technological developments are increasing thermal loads that require faster cooling. The conventional methods of enhancing the cooling rate are already stretched to their limits [6–10]. Hence, there is need for new and innovative cutting fluids to achieve this high performance cooling [11, 12].

Nano-cutting fluid is one of the novel concepts, wherein nanoparticles are suspended in conventional cutting fluid, which are being developed to meet more demanding cooling and lubricating challenges in machining. Several researchers showed that the convective heat transfer coefficient increases substantially for nanofluids [13–18].

The present work aims at demonstrating the possibility of enhancing the desired properties of a cutting fluid by adding suitable nanoparticles and forming stable nano-cutting fluids. Recent studies indicated that suspended nanoparticles can alter the thermophysical and transport properties of the conventional cutting fluids. A small amount of copper nanoparticles (less than 1% vol. fraction) or carbon nanotubes dispersed in ethylene glycol can increase the poor thermal conductivity of ethylene glycol by 40% to 150%. The thermal conductivity of nanofluids increases nonlinearly with temperature [19]. Kim and Bang show that addition of nanoparticles enhances the wettability of the base fluids

[20]. Nanoparticles near the liquid-solid surface can enhance the wettability characteristics of the base fluid [21–23].

Thus, the introduction of nano-cutting fluids has opened up the new possibility of enhancing the thermo-physical properties of the base fluids in a desired manner. In tune with emerging trends, the present study reports the successful application of Al_2O_3 based nano-cutting fluids for machining operation.

In the present study, a special type of nano-cutting fluid is developed by mixing self-synthesized Al_2O_3 nano particles into the conventional cutting fluid. The wettability of water, conventional cutting fluid, and nano-cutting fluids is measured using macroscopic contact angle method. The comparative wettability study is to demonstrate the better wettability characteristics of nano-cutting fluids compared to other two fluids. Later, cutting performance is compared among dry machining, machining with conventional cutting fluid, and nano-cutting fluid in terms of tool wear (crater wear and flank wear), cutting force, average surface roughness, and chip thickness.

EXPERIMENTATION

Materials Selection and Equipment

Various equipments and materials (with their specifications) that are used in the present experimental study are given in the Table 1.

Selection of Input Parameters

The input parameters for the present study are selected and given in the Table 2.

Formulation of Nano-Cutting Fluid

The nano-cutting fluid is prepared by adding 1% by volume of self-synthesised Al_2O_3 nanoparticles to the emulsion type cutting fluid (Servo-Cut-‘S’). Later, this

Cutting tool	Uncoated cemented carbide insert (TPUN 16-03-08)
Machine tool	LB/17 Lathe (HMT, India)
Cutting fluid	Servo Cut “S” + Additives + Al ₂ O ₃ nanoparticles + Water
Surf analyzer	Surf Analyzer 5000 (Federal)
Tool wear analyzer	Scanning electron microscope, Optical microscope

mixture is subjected to ultrasonication for about two hours. It results in a stable nano-cutting fluid and no precipitation/settlement of particles is observed during entire machining process.

Experimental Procedure

Preliminary experimentation is carried out for dry machining and machining with conventional and nano-cutting fluids to find the optimum range of various input parameters, i.e., feed rate, cutting velocity, and depth of cut (Table 2). Later, complete experiments are carried out in dry machining and machining with conventional and nano-cutting fluids conditions, respectively, to find the relative advantage of nano-cutting fluid over the other two.

Cutting force (F_C) during the machining trials is recorded with the aid of a piezoelectric tool-post dynamometer. Surface roughness values of the machined workpiece at five locations are recorded using a stylus type surface profilometer (Federal Surf Analyzer 5000). The average of five surface roughness values is calculated and represented as the average surface roughness (R_a) value of the machined surface. Flank wear measurement and morphology is studied using optical microscope. Chip thickness and chip morphology is also analyzed for comparison of three machining processes.

RESULTS AND DISCUSSION

Wettability Study of Nano-Cutting Fluid

The wettability characteristics of fluid on a particular solid substrate can be estimated by the measurement of macroscopic contact angle between the fluid droplet and the solid substrate surface. In most applications, air is always present as the third phase. Thus, the equilibrium thermodynamic contact angle is given by Young's equation (Fig. 1) [24]:

$$\cos \theta = \frac{\sigma_{sv} - \sigma_{sl}}{\sigma_{lv}} \quad (1)$$

TABLE 2.— Process input parameters

Cutting time (t)	50, 100, 150, 200, 250, 300, 350 (sec)
Feed (f)	0.1 (mm/rev)

Depth of cut (d)	1.0 (mm) (radially)
Machining environments	(i) dry machining (ii) Machining with conventional cutting fluid (iii) Machining with nano-cutting fluid

FIGURE 1.—Schematic showing a droplet of liquid on a solid surface.

Alternatively, the macroscopic contact angle can also be viewed as the manifestation of the interaction of adhesive/cohesive forces acting on the contact line, i.e.,

$$\cos \theta = \frac{\text{Net adhesion force}}{\text{Surface tension force}} \quad (2)$$

From a thermodynamic point of view, spreading of the liquid droplet ensures minimization of Helmholtz free energy, leading to the definition of equilibrium contact angle, i.e.,

$$\frac{\partial F_H}{\partial A_{sl}} = \sigma_{sl} + \sigma_{lv} - \sigma_{sv} \quad (3)$$

The free energy of a system depends on the intermolecular force potentials of the constituent molecules/atoms (van der Waals forces, Debye forces, Keesom forces, Hydrogen bonds, Covalent bonds, etc.). These interactive forces also give rise to the phenomenon of surface tension. It is known that the net surface tension of liquids strongly depends on the Van der Waals forces. The interaction length scale of these forces is of the order of 1 nm to 100 nm, which is the size of the nanoparticles. So, it is expected that addition of nanoparticles affects the net free energy of a pure fluid-solid-air interface.

To check this hypothesis, macroscopic contact angles of pendant droplets of pure water, conventional cutting fluid, and nano-cutting fluid, respectively, are measured by a goniometer on a cutting tool insert (TPUN 16-03-08). It is clearly seen that the wettability of nano-cutting fluid is substantially better than that of pure water and conventional cutting fluid (Fig. 2). All the measurements are performed at room temperature (27°C), and the droplet volume of 10 µl is used. Droplet sizes in all measurements are ensured by a micrometering syringe. The repeatability of the contact angle data is observed within ±5%.

The data clearly suggest that the nanoparticles affect the adhesive/cohesive force interactions at the contact line. Also, the wetting area per unit volume in the case of nano-cutting fluid droplet increases. So, it enhances

FIGURE 2.—Images of pendant droplets of (a) pure water, (b) conventional cutting fluid, and (c) nano-cutting fluid on carbide tool substrate.

the lubricating and heat removal properties compared to the conventional cutting fluid.

Tool Wear

In the present study, tool wear refers to the morphology of crater and flank wears. The temperature generated in the primary and secondary shear zone affects the wear of tool materials. The existence of high cutting temperature and stress at the cutting edge, coupled with the brittleness of the tool material, accelerates the chipping, cracking, and fracture of the tool inserts. This is commonly seen in dry machining process due to the absence of cutting fluid. So, crater wear is high in dry machining (Fig. 3(a)). Due to continuous rubbing of the machined work surface on the thermally softened flank face and absence of cutting fluid leads to severe flank wear (Fig. 3(b)).

Conventional cutting fluids provide lubrication and partially reduce the generated heat in machining zone compared to dry condition. But due to dominant adhesive wear mode, crater wear is observed near the tool cutting edge. Adhesive wear mechanism depends on the adhesive affinity of tool and workpiece, the hot strength of the tool material at the adhesive junction, and the frequency of interruptions at the adhesive contact. Weak interface bonding between tool and workpiece surfaces increase the severity of adhesion wear. The adhered workpiece surface layer often remains attached to the tool edge. Thus the crater wear is observed at the seizure zone of machining (Fig. 3(c)). Continuous rubbing of workpiece with the flank face tries to chip-off tool flank surface layers. But, because of conventional cutting fluid lubrication ability, the tool retains its hardness and thus flank wear partially reduces compared to dry machining process (Fig. 3(d),(e)). In case of nano-cutting fluid, because of its better conduction, convection, and wettability compared to conventional cutting fluid, both tool wears (crater and flank wear) reduce enormously and are just confined minimally to cutting edge region only. Due to better cooling and lubrication properties of nano-cutting fluid, the tool retains its original hardness for longer times (Fig. 3(f)). Thus the flank wear is minimum compared to the other two processes (Fig. 3(g)).

Cutting Force

As machining starts, in the initial stage the cutting forces are less as the tool is sharp and machining is

FIGURE 3.—Crater and flank wear in (a-b) dry turning, (c-d) turning with conventional cutting fluid, and (e-f) turning with Al_2O_3 based nano-cutting fluid (color figure available online).

smooth. As machining time increases, the cutting edge wear gradually increases (sharpness decreases) either by deformation or by chipping. Thus, the cutting force also increases with machining time.

Figure 4 shows the variation of the cutting force with machining time. As the machining time increases, the cutting edge wears out gradually, irrespective of the presence or absence of the cutting fluid. Due to the absence of cutting fluid in dry machining, tool cutting edge wears out early because of the quick thermal softening of the cutting tool material in the machining zone. This leads to rapid increase in cutting force which is clearly seen around ~ 120 s (Fig. 4). The presence of conventional cutting fluid improves the life of cutting edge by providing cooling and lubrication (through conduction and convection process). So, tool hardness is retained for more time and rapid increase in the cutting force is observed around ~ 210 s of machining time. But in case of the nano-cutting fluid, rapid increase in cutting force is not observed because of improved cooling and lubrication. Though there is a continuous increase in the cutting force from the start of machining, while machining with nano-cutting fluids, cutting force magnitude is smaller as compared to other techniques (Fig. 4).

FIGURE 4.—Variation of cutting force with machining time for dry machining and machining with conventional and nano-cutting fluids.

Chip Morphology and Chip Thickness

In dry machining process, because of the high temperature in the shear zone, the work and tool materials get thermal softening. Since the workpiece material is much softer compared to the tool material, the continuous helical chips are generated. These chips try to weld to the top surface layers of tool rake face and take away thermally softened tool rake surface layers. Thus the chip thickness is high in dry machining process (Fig. 5). While machining with conventional cutting fluid, a hydrodynamic cutting fluid layer forms between chip and tool rake face. This hydrodynamic cutting fluid layer tries to push the chip away from the rake face. So, chip helix angle increases and even sometimes breaks the chip after a certain length. Thus, the chips are semilong with more helix angle (Fig. 5). In machining with nano-cutting fluid, due to impingement of Al_2O_3 nanoparticles on the chips, longer chips are forced to break, and this leads to tiny segmented chips. Nano-cutting fluid provides better cooling and lubricating properties which reduce the possibility of crater wear (Fig. 3(f)) and sticking of tool material on the back side of the chip; hence, chip

FIGURE 5.—Effect of feed on chip thickness during dry machining and machining with conventional cutting fluid as well as nano-cutting fluid (color figure available online).

FIGURE 6.—Variation of average surface roughness while dry machining and machining with conventional and nano-cutting fluid.

thickness is less when compared to the other two machining techniques (Fig. 5).

Surface Roughness

In the dry machining process, because of the absence of cutting fluid, the cutting edge wear occurs rapidly. So the machining process is no more smooth and the R_a generated on the workpiece surface is high (Fig. 6). When machining with conventional cutting fluid, the cutting fluid presence protects the cutting edge partially due to its cooling and lubrication properties. So, the machining process is partially smooth and thus the R_a generated is better compared to dry machining, (i.e., surface roughness reduces partially). But nano-cutting fluid greatly improves the wetting/lubricating properties of rake and flank regions. The net effect leads to better heat dissipation, so the machining process is smoother and causes retaining of hardness of tool cutting edge. Hence the surface roughness achieved during machining with nano-cutting fluid is minimum compared to other two machining conditions (Fig. 6).

SUMMARY AND CONCLUSIONS

In the present article, a comparative study of the performance during dry machining and machining with conventional and nano-cutting fluids is reported. It also investigates the effect on wettability characteristics of base fluids when nanoparticles are added. The following conclusions can be drawn based on the present work:

- It is found that adding 1% Al_2O_3 nanoparticles (by volume) to the conventional cutting fluid greatly enhances its wettability characteristics compared to pure water and conventional cutting fluid.
- The great reduction of crater and flank wear is attributed to enhanced thermal properties, improvement in wettability, and lubricating characteristics of the nano-cutting fluid.
- There is a reduction of $\sim 50\%$ and $\sim 30\%$ cutting force while machining with nano-cutting fluids

compared to dry machining and machining with conventional cutting fluid, respectively.

- d. There is 54.5% and 28.5% reduction in the R_a value of the machined surface when nano-cutting fluid is used compared to dry machining and machining with conventional cutting fluid, respectively.
