1. INTRODUCTION

Among the major recent developments in understanding the structures of objects found in nature, the notion of fractals occupies an important place. Since the introduction of the term Fractal by Mandelbrot, an increasing number of research papers have demonstrated the fractal nature of many systems with different physical properties. Fractal dimension is widely used to quantify the roughness of natural objects and structures. It was demonstrated by Mandelbrot himself that the notion of fractal dimension is quite useful in quantifying the roughness of irregular patterns such as that of tortuous lines, crumpled surfaces, intricate shapes.
Breslin and Belward\textsuperscript{3} used fractal dimension to model rainfall time series and discussed suitability of fractal analysis for these type of data. Arakawa and Krotkov\textsuperscript{4} discussed natural terrain modeling using fractal geometry and gave methods of estimation of fractal dimension and fractal surface reconstruction. Lung and Zhang\textsuperscript{5} discussed the origin of the negative correlation between fractal dimension and toughness of fractured surfaces of materials. Zahnouni \textit{et al.}\textsuperscript{6} modeled a random surface topography and showed that fractal dimension can be used as an indicator of the real values of different scale-dependent parameters such as length, surfaces and volume of roughness.

Barnsley and Harrington\textsuperscript{7} used shifted composition to express affine Fractal Interpolation Functions (FIFs) and computed their fractal dimensions. Bedford\textsuperscript{8} extended Barnsley’s definition of self-affine fractal function to use non-linear scalings and showed that for a class of such functions, the Hölder exponents are related to the box dimension of the function. However, most of the natural objects like surfaces of rocks, sea surfaces, clouds and many naturally occurring structures are made up of both self-affine and non-self-affine parts. In most of the cases, the computation of fractal dimension of these surfaces by existing methods is not practically feasible. The present work is aimed at overcoming this inadequacy by finding the bounds on Fractal Dimension of a Coalescence Hidden Fractal Interpolation Surface (CHFIS), which is generated from a non-diagonal IFS on an equispaced mesh that generates both self-affine and non-self affine FIS simultaneously, depending on free variables and constrained variable.

The organization of the paper is as follows: A brief introduction on construction of CHFIS and its smoothness is given in Sec. 2. Our main results on bounds of Fractal Dimension of CHFIS on equispaced mesh are derived in Sec. 3. Using these bounds, certain conditions on the free parameters are determined that lead the fractal dimension of the constructed CHFIS to become close to 3. Finally, in Sec. 4, to substantiate our results, the bounds on fractal dimension of CHFIS of a Tsunami wave surface are computed.

2. CONSTRUCTION OF CHFIS

Let \(\{(x_0, y_0, z_0), (x_1, y_0, z_0), \ldots, (x_0, y_1, z_0), \ldots, (x_0, y_N, z_0), \ldots, (x_0, y_N, z_N, N)\}, N \in \mathbb{N}\) be an interpolation data in \(\mathbb{R}^3\) such that \(x_0 < x_1 < \cdots < x_N, y_0 < y_1 < \cdots < y_N\) and the independent variables on \(X\) and \(Y\) axis are equally spaced on a square mesh \([0, 4] \times [0, 4]\). For the construction of Coalescence Hidden Fractal Interpolation Surface (CHFIS), a set of real parameters \(\{\varepsilon_{i,j}\}\), called hidden-variables, are introduced and the generalized interpolation data \(\{(x_i, y_i, z_i, t_i), i, j = 0, 1, \ldots, N\}\) is considered. Define the Iterated Function System (IFS)

\[
\{\mathbb{R}^4, \omega_{n,m} = (\phi_n, \psi_m, G_{n,m}(x, y, z, t)), n, m = 1, 2, \ldots, N\},
\]

where the functions \(\phi_n : [x_0, x_N] \rightarrow [x_{n-1}, x_n]\), \(\psi_m : [y_0, y_N] \rightarrow [y_{m-1}, y_m]\) are

\[
\begin{align*}
\phi_n(x) &= x_{n-1} + \frac{x_n - x_{n-1}}{x_N - x_0}(x - x_0), \\
\psi_m(y) &= y_{m-1} + \frac{y_m - y_{m-1}}{y_N - y_0}(y - y_0)
\end{align*}
\]

and the function \(G_{n,m} : [x_0, x_N] \times [y_0, y_N] \times \mathbb{R}^2 \rightarrow \mathbb{R}^2\) is

\[
G_{n,m}(x, y, z, t) = \begin{cases} F_{n+1,m}(x_0, y_0, z, t), & x = x_N, n = 1, \ldots, N - 1, \\
F_{n,m+1}(x_0, y_0, z, t), & y = y_N, n = 1, \ldots, N, \\
F_{n,m}(x, y, z, t), & \text{otherwise},
\end{cases}
\]

with the function \(F_{n,m}(x, y, z, t) = (F_{n,m}^1(x, y), F_{n,m}^2(x, y))\) given by

\[
\begin{align*}
F_{n,m}^1(x, y, z, t) &= \alpha_{n,m} z + \beta_{n,m} t + \epsilon_{n,m} x + f_{n,m} y + g_{n,m} (z + \epsilon_{n,m} y + \kappa_{n,m}), \\
F_{n,m}^2(x, y, z, t) &= \gamma_{n,m} t + \epsilon_{n,m} x + f_{n,m} y + g_{n,m} (z + \epsilon_{n,m} y + \kappa_{n,m}).
\end{align*}
\]

In Eq. (2.2), \(\alpha_{n,m}\) and \(\gamma_{n,m}\) are free variables chosen such that \(|\alpha_{n,m}| < 1\) and \(|\gamma_{n,m}| < 1\) and \(|\beta_{n,m}|, |\epsilon_{n,m}|, |f_{n,m}|, |g_{n,m}|, \) \(|\kappa_{n,m}|\) is a constrained variable chosen such that \(|\beta_{n,m}| + |\epsilon_{n,m}| < 1\) and the real coefficients \(\epsilon_{n,m}, f_{n,m}, g_{n,m}, \) \(\kappa_{n,m}\) are obtained by the join-up conditions:

\[
\begin{align*}
F_{n,m}(x_0, y_0, z_0, t_0) &= (\varepsilon_{n-1,m-1}, t_{n-1,m-1}) \\
F_{n,m}(x_N, y_0, z_N, t_N) &= (\varepsilon_{n,m-1}, t_{n,m-1}) \\
F_{n,m}(x_0, y_M, z_0, t_M) &= (\varepsilon_{n-1,m}, t_{n-1,m}) \\
F_{n,m}(x_N, y_M, z_N, t_M) &= (\varepsilon_{n,m}, t_{n,m}).
\end{align*}
\]
It is known\(^9\) that there exists a metric \(\tau\) on \(\mathbb{R}^3\), equivalent to the Euclidean metric, such that the IFS, given by Eq. (2.1), is hyperbolic with respect to the metric \(\tau\) and there exists a unique non-empty compact set \(G \subseteq \mathbb{R}^3\) with respect to the metric \(\tau\) such that \(G = \bigcup_{i=1}^{N} \omega_{n,m}(G)\). The set \(G\), called the attractor of the IFS for the given interpolation data, is the graph of a continuous function \(F : [x_0, x_N] \times [y_0, y_N] \to \mathbb{R}^3\) such that \(F(x, y) = (x_i, F(x_i), y_i)\), \(i = 0, \ldots, N\). \(F\) is said to be a Little Fatou \(\delta\) for \(X\) and \(Y\), the graph of \(F(x, y)\) is defined as \(\Gamma = \{(x, y, F(x, y)) : (x, y) \in [x_0, x_N] \times [y_0, y_N]\} \). Now, expressing the function \(F(x, y)\) component-wise as \(F(x, y) = (F_1(x, y), F_2(x, y))\), the Coalescence Hidden-variable Fractal Interpolation Surface (CHFIS) for the given interpolation data is defined as follows:

**Definition 2.1.** The Coalescence Hidden-variable Fractal Interpolation Surface (CHFIS) for the given interpolation data \(\{(x_i, y_i, z_i) : i = 0, \ldots, N\}\) is defined as the function \(F_1((x, y))\) whose projection is the graph of \(F((x, y))\) on \(\mathbb{R}^3\).

A set \(S\) of points \(x = (x_1, x_2, \ldots, x_n)\) in a Euclidean space of dimension \(n\) is called self-affine if \(S\) is union of \(N\) distinct subsets, each identical with \(aS = \{(a_1x_1, a_2x_2, \ldots, anx_n) : a = (a_1, a_2, \ldots, an)\}\). \(a \geq 0\) and \(x \in S\) up to translation and rotation. If \(S\) is not self-affine, then it is called non-self-affine. The function \(F_1((x, y))\) occurring in Definition 2.1 is called a CHFIS as it exhibits both self-affine and non-self-affine nature. We observe that the function \(F_1((x, y))\) for the same interpolation data is always a self-affine function.

Fractal Dimension of a CHFIS \(F_1((x, y))\) is the box counting dimension\(^{10}\) of its graph defined as:

\[
\text{Dim}(\Gamma) = \lim_{n \to \infty} \frac{\log(N_r(\Gamma))}{\log(\frac{1}{n})}
\]

provided the limit exist, \(N_r(\Gamma)\) being the smallest number of boxes in \(\mathbb{R}^2\) of side \(\frac{1}{n}\) that intersect the graph of CHFIS \(F_1((x, y))\).

A function \(F : \mathbb{R}^2 \to \mathbb{R}\) is said to be a Lipshitz function of order \(\delta\) (written as \(\text{Lip}_\delta\)) if \(|F(x) - F(\bar{x})| \leq K|d(x, \bar{x})|^\delta\) where, \(K\) is a constant, \(\delta \in (0, 1]\) and \(d(x, \bar{x}) = |x - \bar{x}| + |y - \bar{y}|\) for \(x = (x, y), \bar{x} = (\bar{x}, \bar{y})\). The function \(F\) is said to be a Lip\(\delta\) function, if \(|F(X) - F(\bar{X})| \leq K|d(X, \bar{X})|^\delta\) where \(K\) is a constant, \(\delta \in (0, 1]\) and \(d(X, \bar{X}) = |x - \bar{x}| + |y - \bar{y}|\) for \(X = (x, y), \bar{X} = (\bar{x}, \bar{y})\). It is observed that the functions \(\phi_{n,m}(x, y)\) and \(\psi_{n,m}(x, y)\), given by Eq. (2.4), belong to the classes Lip \(\lambda_{n,m}\) and Lip \(\mu_{n,m}\) \((0 < \lambda_{n,m}, \mu_{n,m} \leq 1)\) respectively.

The following notations are used in the sequel.

**Notations.** \(I = [x_0, x_N]\); \(J = [y_0, y_N]\); \(I_n = [x_{n-1}, x_n]\) \(J_n = [y_{n-1}, y_n]\); \(\text{Imin} = \min\{|I_n| : n = 1, \ldots, N\}\); \(\text{Imax} = \max\{|I_n| : n = 1, \ldots, N\}\); \(\text{Jmin} = \min\{|J_n| : n = 1, \ldots, N\}\); \(\text{Jmax} = \max\{|J_n| : n = 1, \ldots, N\}\); \(\text{Sn,m} = I_n \times J_m; \text{Smin} = \text{Imin} \times \text{Jmin} = \min\{|I_n| \text{times } |J_m| : n = 1, \ldots, N\}; \text{Smax} = \text{Imax} \times \text{Jmax} = \max\{|I_n| \text{times } |J_m| : n = 1, \ldots, N\}; \text{\Omega}_{n,m} := \text{\Gamma}_{n,m} = (x_{n-1}, y_{n-1}) \times (x_n, y_n); \text{\Theta}_{n,m} := (x_{n-1}, y_{n-1}) \times (x_n, y_n).\) Further, we denote

\[
\text{Imax} \times \text{Jmax}; \text{Imin} \times \text{Jmin}; \text{Imin} \times \text{Jmax}; \text{Imax} \times \text{Jmin}
\]

**Definition 2.2.** The Bivariate CHFIS \(F_2((x, y))\) is called a Critical CHFIS if any one of the conditions \(\Omega = 1\), \(\Gamma = 1\), and \(\Theta = 1\) holds.

### 3. Fractal Dimension of CHFIS

In this section, the bounds on the fractal dimension of CHFIS \(F_2((x, y))\) for different critical cases are obtained in Theorems 3.1 and 3.2. Using these bounds, certain conditions on the free parameters are determined that lead the fractal dimension of the constructed CHFIS to become close to 3. Also, these bounds give us a range of the free parameters that ensure the fractal dimension of the constructed CHFIS to be strictly greater than 2. Let \(I_{r_1, \ldots, r_k} = I_{r_1} \times I_{r_2} \times \cdots \times I_{r_k}\) and \(J_{s_1, \ldots, s_l} = J_{s_1} \times J_{s_2} \times \cdots \times J_{s_l}\) denote the length of the intervals \(I_{r_i}\) and \(J_{s_j}\) respectively. Hence, the area of square \(S_{r_1, \ldots, r_k, s_1, \ldots, s_l}\) is \(I_{r_1} \times I_{r_2} \times \cdots \times I_{r_k} \times J_{s_1} \times J_{s_2} \times \cdots \times J_{s_l}\) and the diameter \(d_{r_1, \ldots, r_k, s_1, \ldots, s_l}\) of the square \(S_{r_1, \ldots, r_k, s_1, \ldots, s_l}\) is \(d_{r_1, \ldots, r_k} + d_{s_1, \ldots, s_l}\).
Theorem 3.1. Let \( F_i(x, y) \) be a CHFIS with \( \Theta \neq 1 \). Then, for the critical condition \( \Omega = 1 \),
\[
\zeta(\alpha_\ast) \leq D(\text{Graph}(F_i(x, y))) \leq 3 - \delta(\Gamma) \tag{3.1}
\]
where \( \zeta(\alpha_\ast) = \max\{1 + \log(\sum_{i=1}^{N} \frac{\sum_{j=1}^{m} |\zeta(\alpha_\ast)|}{\log N} \}, 2 \} \), and \( \delta(\Gamma) \in (0, 1). \) Further, for the critical condition \( \Gamma = 1 \),
\[
\eta(\gamma_\ast) \leq D(\text{Graph}(F_i(x, y))) \leq 3 - \delta(\Omega), \tag{3.2}
\]
where \( \eta(\gamma_\ast) = \max\{1 + \log(\sum_{i=1}^{N} \frac{\sum_{j=1}^{m} |\eta(\gamma_\ast)|}{\log N} \}, 2 \} \), and \( \delta(\Omega) \in (0, 1). \)

Proof. Case (i): \( \Theta \neq 1, \Omega = 1 \) and \( \Gamma \neq 1 \) In this case, there exist constants \( C_1 \) and \( C_2 \) such that
\[
C_1(d_{M}(X, \bar{X}))^{\delta(\Gamma)} \leq d_{M}(F_i(x, y)) \leq C_2(d_{M}(X, \bar{X}))^{\delta(\Gamma)} \times [1 + \log(d_{M}(X, \bar{X}))], \tag{3.3}
\]
for some \( \delta(\Gamma) \in (0, 1), X = (x, y), \bar{X} = (\bar{x}, \bar{y}), \) \( 0 \leq x < \bar{x} \leq \frac{1}{2} \) and \( 0 \leq y < \bar{y} \leq \frac{1}{2} \). In fact, \( \delta(\Gamma) = \min(\lambda, \mu) \) or \( \min(\lambda, \tau_1) \) if \( \Gamma \leq 1 \) and \( \delta(\Gamma) = \min(\lambda, \tau_2) \) or \( \delta = \min(\lambda, \tau_3) \) if \( \Gamma > 1 \), where, \( \tau_1, \tau_2 \) and \( \tau_3 \) are non-negative real numbers in the interval \( (0, 1) \) such that \( \tau_1 \leq \frac{\log(\min(\lambda, \mu))}{\log N}, \tau_2 \leq \frac{\log(\min(\lambda, \tau_1))}{\log N}, \) \( \tau_3 \leq \frac{\log(\min(\lambda, \tau_2))}{\log N} \).

Let \( \Gamma = \min(\lambda, \mu) \), \( \Gamma = \min(\lambda, \tau_1) \) or \( \Gamma = \min(\lambda, \tau_2) \) or \( \Gamma = \min(\lambda, \tau_3) \) if \( \Gamma > 1 \), respectively.

Then, \( \max\{d_{M}(X, \bar{X})\} = \min(\lambda, \mu) \) or \( \min(\lambda, \tau_1) \) or \( \min(\lambda, \tau_2) \) or \( \min(\lambda, \tau_3) \) if \( \Gamma > 1 \), respectively.

\[
C_1\left( \frac{\log(\min(\lambda, \mu))}{\log N} \right) \leq \frac{C_2\left( \frac{\log(\min(\lambda, \tau_1))}{\log N} \right)}{1 + \log(\min(\lambda, \tau_1))} \times \left[ \frac{1 + \log(\min(\lambda, \tau_1))}{\log N} \right].
\]

The above inequality implies
\[
C_1 N^m \left[ \sum_{i=1}^{N} \sum_{j=1}^{m} |\alpha_{i,j}| \right] \leq N (\text{Graph}(F_i(x, y))) \leq \left( C_2 \frac{\log(\min(\lambda, \mu))}{\log N} \right) \times \left[ \frac{1 + \log(\min(\lambda, \tau_1))}{\log N} \right].
\]

The bound on fractal dimension of CHFIS \( F_i(x, y) \) given by Eq. (3.1) follow from the above inequalities and \( \zeta(\alpha_\ast) = \max\{1 + \log(\sum_{i=1}^{N} \frac{\sum_{j=1}^{m} |\zeta(\alpha_\ast)|}{\log N} \}, 2 \} \).

Case (ii): \( \Theta \neq 1, \Omega = 1 \) and \( \Gamma \neq 1 \) The proof is similar to case (i) up to Eq. (3.4). In the present case, since \( \Gamma = 1, \tau_1, \tau_2 \leq \left( \frac{\log(\min(\lambda, \mu))}{\log N} \right) \leq \left( \frac{\log(\min(\lambda, \tau_1))}{\log N} \right) \), where, \( \delta(\Omega) \in (0, 1) \) is given by \( \delta(\Omega) = \min(\lambda, \mu) \) or \( \min(\lambda, \tau_1) \) or \( \min(\lambda, \tau_2) \) or \( \min(\lambda, \tau_3) \) if \( \Omega > 1 \), respectively.

\[
\prod_{i=1}^{m} |\gamma_{i,j}| \leq C_1 N^m \left[ \sum_{i=1}^{N} \sum_{j=1}^{m} |\gamma_{i,j}| \right] \leq \left( \frac{\log(\min(\lambda, \mu))}{\log N} \right) \times \left[ \frac{1 + \log(\min(\lambda, \tau_1))}{\log N} \right].
\]
Therefore, it follows from (3.4),
\[ C_1 \prod_{i=1}^{m} |\gamma_{r,s}| \leq |G_{r_1,r_2,\ldots,r_m,s_1,s_2,\ldots,s_m}| \]
\[ \leq C_2 \left( \frac{1}{N} \right)^{m(\delta(\Omega)-1)} \left[ 1 + \log \left( \frac{1}{N} \right) \right]^m. \]
Taking summation over \( r_1, r_2, \ldots, r_m \) and \( s_1, s_2, \ldots, s_m \) from 1 to \( N \), we have
\[ C_1 N^m \sum_{r_1,\ldots,r_m} \sum_{s_1,\ldots,s_m} |\gamma_{r,s}| \]
\[ \leq N^m \sum_{r_1,\ldots,r_m} \sum_{s_1,\ldots,s_m} |G_{r_1,\ldots,r_m,s_1,\ldots,s_m}| \]
\[ \leq \left\{ C_2 \left( \frac{1}{N} \right)^{m(\delta(\Omega)-1)} \left[ 1 + \log \left( \frac{1}{N} \right) \right]^m \right\} \times \sum_{r_1,\ldots,r_m} \sum_{s_1,\ldots,s_m} 1. \]
The above inequality implies
\[ C_1 N^m \left[ \sum_{i=1}^{N} \sum_{j=1}^{N} |\gamma_{i,j}| \right]^m \]
\[ \leq N \alpha \left( \text{Graph}(F_1(x,y)) \right) \]
\[ \leq \left\{ C_2 \left( \frac{1}{N} \right)^{m(\delta(\Omega)-1)} \left[ 1 + \log \left( \frac{1}{N} \right) \right]^m \right\} \cdot N^m. \]
The bound on fractal dimension of CHFIS \( F_1(x,y) \) given by Eq. (3.2) follow from the above inequalities and \( \alpha(\gamma_{r,s}) = \max \{ 1 + \frac{\log N \sum_{i=1}^{N} \sum_{j=1}^{N} |\gamma_{i,j}|}{\log N}, 2 \} \).

Theorem 3.2 give us the bounds on the fractal dimension of CHFIS \( F_1(x,y) \) when \( \Theta = 1 \).

**Theorem 3.2.** Let \( F_1(x,y) \) be a CHFIS with \( \Theta = 1 \). Then,
\[ \zeta(\alpha_{r,s}) \leq D_F(\text{Graph}(F_1(x,y))) \leq 3 - \delta(\Omega, \Gamma), \]
(3.5)
where \( \zeta(\alpha_{r,s}) = \max \{ 1 + \frac{\log N \sum_{i=1}^{N} \sum_{j=1}^{N} |\gamma_{i,j}|}{\log N}, 1 \} \) and \( \delta(\Omega, \Gamma) \in (0,1] \).

**Proof.** Since \( \Theta = 1 \), \( \Theta_{r,s} \leq \Theta = 1 \) implies \( |\alpha_{r,s}| \leq |(S_{r,s})|^p \leq (S_{r,s})^{\delta(\Omega, \Gamma)} \), where,
(i) \( \delta(\Omega, \Gamma) = \min(\lambda, \mu) \) for \( \Omega \leq 1, \Gamma \leq 1 \),
(ii) \( \delta(\Omega, \Gamma) = \min(\tau_1, \mu) \) for \( \Omega > 1, \Gamma \leq 1 \),
(iii) \( \delta(\Omega, \Gamma) = \min(\lambda, \tau_2) \) for \( \Omega \leq 1, \Gamma > 1 \) and
(iv) \( \delta(\Omega, \Gamma) = \min(\tau_1, \tau_2) \) for \( \Omega > 1, \Gamma > 1 \).

$\Omega = 1$ or $\Gamma = 1$ for the simulation of the tsunami wave surface as a CHFIS. The values of these parameters are determined by requiring that the functions $p_{n,m}$ and $q_{n,m}$ defined by Eq. (2.4) are in suitable classes Lip $\lambda_{n,m}$ and Lip $\mu_{n,m}$ respectively such that the value of $\Theta$, $\Omega$ or $\Gamma$ (c.f. Eq. (2.5)) equals 1. The last three columns in Table 3 give corresponding $\delta$-value of simulated CHFIS, lower bound and upper bound (c.f. Inequalities (3.1), (3.2) and (3.5)) of its fractal dimension. Figures 2(a)–2(c) give the simulations.
of the tsunami wave surface (c.f. Fig. 1) as CHFIS under different critical conditions corresponding to the choices of free parameters in Table 3.

It is observed in Table 3 that the critical condition $\Theta = 1$ gives the largest lower bound on the fractal dimension of the corresponding CHFIS (c.f. Fig. 2(a)) while the critical condition $\Omega = 1$ gives the least upper bound on the fractal dimension of the corresponding CHFIS (c.f. Fig. 2(b)). In case of the critical condition $\Gamma = 1$, the upper and lower bounds on the fractal dimension of the corresponding CHFIS (c.f. Fig. 2(c)) are not the least and largest bounds respectively. Thus, for the above Tsunami wave surface (c.f. Fig. 1) and the generalized interpolation data (c.f. Table 2), the critical condition $\Theta = 1$ or $\omega = 1$ give closer bounds (lower or upper respectively) on the fractal dimension of its simulated CHFIS.

The box counting dimension of the Tsunami wave surface (c.f. Fig. 1) in our present example has also been computed and found to be $2.1377$, substantiating the inequalities (3.1), (3.2) and (3.5).

5. CONCLUSIONS

In this paper, the bounds on Fractal Dimension of Coalescence Hidden-variable Fractal Interpolation Surface (CHFIS) are determined. Using these bounds on Fractal Dimension of CHFIS, certain conditions on the free parameters are found that lead the fractal dimension of the constructed CHFIS to become close to 3. As a test case, a tsunami wave surface (c.f. Fig. 1) in our present example has also been computed and found to be $2.1377$, substantiating the inequalities (3.1), (3.2) and (3.5).
