## **Measure of Central Tendency**

**Data set contains many variables. Every variable has many observations.**

**Difficult to handle each observation and dig out the information from every observation.**

**Our interest is in summary of information hidden inside the data.**

## Measure of Central Tendency

**Example:**

**Suppose the last year's temperature (in degree centegrades) of following two cities in the month of May for 5 days are recorded as follows:**

**Lucknow:        35, 37, 36, 40, 38**

**Srinagar:        20, 18, 17, 22, 23**

**What type of clothings are needed to visit these two cities in the month of May?**

## **Measure of Central Tendency**

**Natural human tendency is to compile the information in term of average.**

**For example, the average marks in a subject in a class are 60%.**

**A medicine tablet controls the fever for 6 hours.**

**Statistical concept refers to the “average” or the central tendency of the data.**

# Measure of Central Tendency

- **Arithmetic mean**
- **Geometric mean**
- **Harmonic mean**
- **Median**
- **Quantiles**
- **Mode etc.**

## Arithmetic Mean for Ungrouped Data

The arithmetic mean of observations  $x_1, x_2, \dots, x_n$  is defined as

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

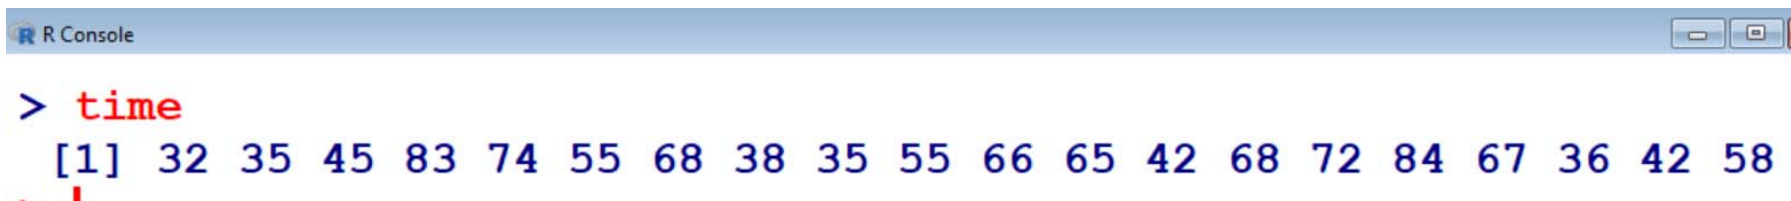

`mean(x)` provides the value of arithmetic mean of the data in data vector **x**.

# Arithmetic Mean Arithmetic Mean for Ungrouped Data

## Example:

Following are the time taken (in seconds) by 20 participants in a race: 32, 35, 45, 83, 74, 55, 68, 38, 35, 55, 66, 65, 42, 68, 72, 84, 67, 36, 42, 58.

```
> time = c(32, 35, 45, 83, 74, 55, 68, 38, 35,  
55, 66, 65, 42, 68, 72, 84, 67, 36, 42, 58)
```

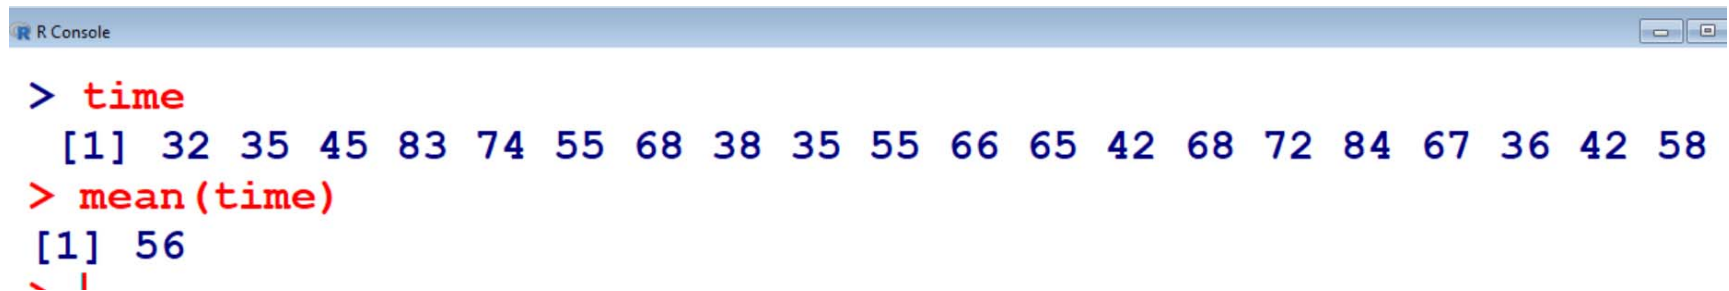

```
R Console  
> time  
[1] 32 35 45 83 74 55 68 38 35 55 66 65 42 68 72 84 67 36 42 58
```

# Arithmetic Mean Arithmetic Mean for Ungrouped Data

Example:

```
> mean(time)
```

```
[1] 56
```

The screenshot shows an R Console window with the following text:

```
R Console  
> time  
[1] 32 35 45 83 74 55 68 38 35 55 66 65 42 68 72 84 67 36 42 58  
> mean(time)  
[1] 56  
~ |
```

# Arithmetic Mean for Ungrouped Data

R command of mean

`mean(x, na.rm = TRUE)` provides the value of arithmetic mean when the data in data vector `x` is not available (`NA`).

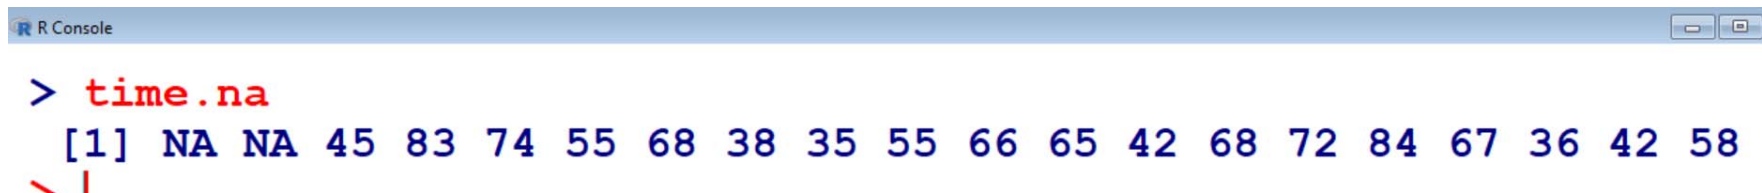

# Arithmetic Mean for Ungrouped Data

## R command of mean : Example

Suppose two data points are missing in the earlier example where the time taken (in seconds) by 20 participants in a race. They are recorded as NA

NA, NA, 45, 83, 74, 55, 68, 38, 35, 55, 66, 65, 42, 68, 72, 84, 67, 36, 42, 58.

```
> time.na = c(NA, NA, 45, 83, 74, 55, 68, 38,  
35, 55, 66, 65, 42, 68, 72, 84, 67, 36, 42, 58)
```

```
R Console  
> time.na  
[1] NA NA 45 83 74 55 68 38 35 55 66 65 42 68 72 84 67 36 42 58  
└─┘
```

# Arithmetic Mean for Ungrouped Data

## R command of mean : Example

```
> mean(time.na)
```

```
[1] NA
```

```
> mean(time.na, na.rm=TRUE)
```

```
[1] 58.5
```

```
> mean(time.na, na.rm=FALSE) # default mean
```

```
[1] NA
```

# Arithmetic Mean for Ungrouped Data

## R command of mean : Example

```
R Console
> time.na
[1] NA NA 45 83 74 55 68 38 35 55 66 65 42 68 72 84 67 36 42 58
> mean(time.na)
[1] NA
> mean(time.na, na.rm=TRUE)
[1] 58.5
> mean(time.na, na.rm=FALSE)
[1] NA
> |
```

# Arithmetic Mean for Ungrouped Data

## R command of mean : Example

Difference between `mean(time)` and `mean(time.na, na.rm=TRUE)`

Mean of 20 values

```
> mean(time)
```

```
[1] 56
```

$$\bar{x} = \frac{1}{20} \sum_{i=1}^{20} x_i$$

Mean of 18 values

```
> mean(time.na, na.rm=TRUE)
```

```
[1] 58.5
```

$$\bar{x} = \frac{1}{18} \sum_{i=1}^{18} x_i$$
