# PIM-SM (protocol independent multicast – sparse mode)

---

- As per RFC4601
- Single shortest path spanning tree
- Rooted at some agreed node – Rendezvous point (RP)
  - The shared tree – called RPT
- To be used for all the group communications

- Independent of routing protocol
- Use unicast routing information base created by the routing protocol
- Alternatively can use multicast routing information base
  - created using unicast routing tables and mBGP.

# Multicast states

- Forwarding states in routers
  - $(*,*)$  - for all groups, from any source
  - $(*,G)$  – for group  $G$ , from any source
  - $(S,G)$  – for group  $G$ , from source  $S$
  - $(S,G,rpt)$  – for group  $G$ , from Source  $S$ , on rendezvous point tree
    - Usually this means that for child nodes specified for this entry, the packets from  $S$  for this group  $G$  are not forwarded

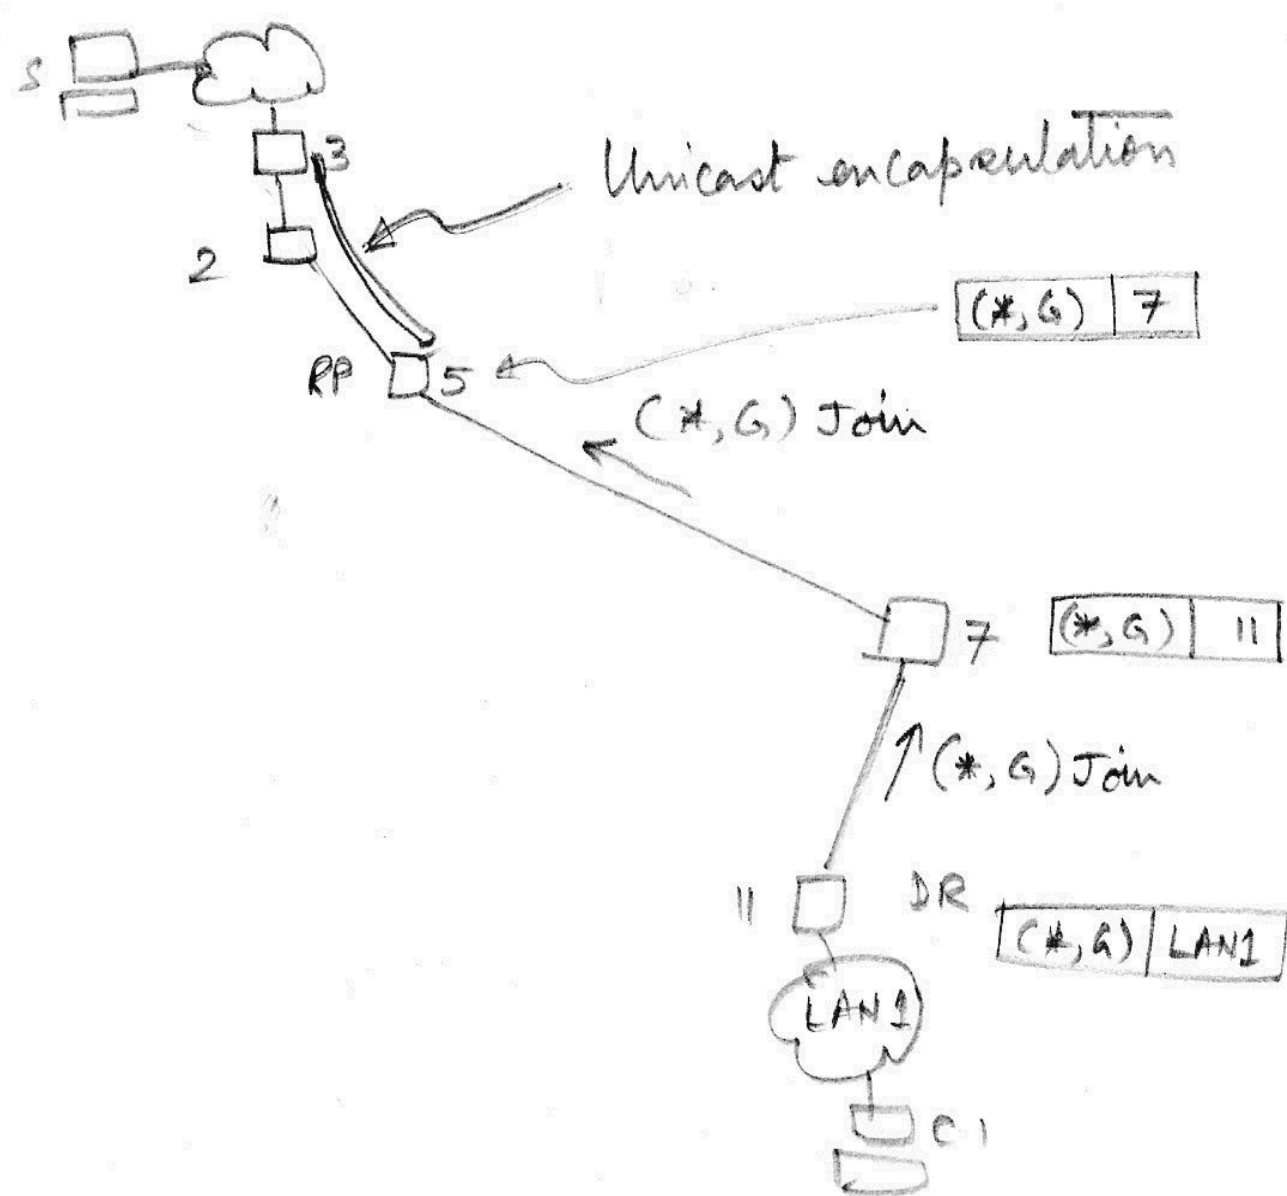

# Phase-I: RP Tree

---

- Receiving endpoint request DR (designated router) – for subscription to G.
- DR creates state for  $(*,G)$  join
- DR send  $(*,G)$  to the router in direction of RP

- For G in SSM multicast range (232.0.0.0-232.255.255.255)
  - Any (\*,G) join will be dropped
  - Only (S,G) join is permitted
- For any source multicast (ASM) (all multicast addresses other than SSM)
  - (\*,G) and (S,G) joins permitted

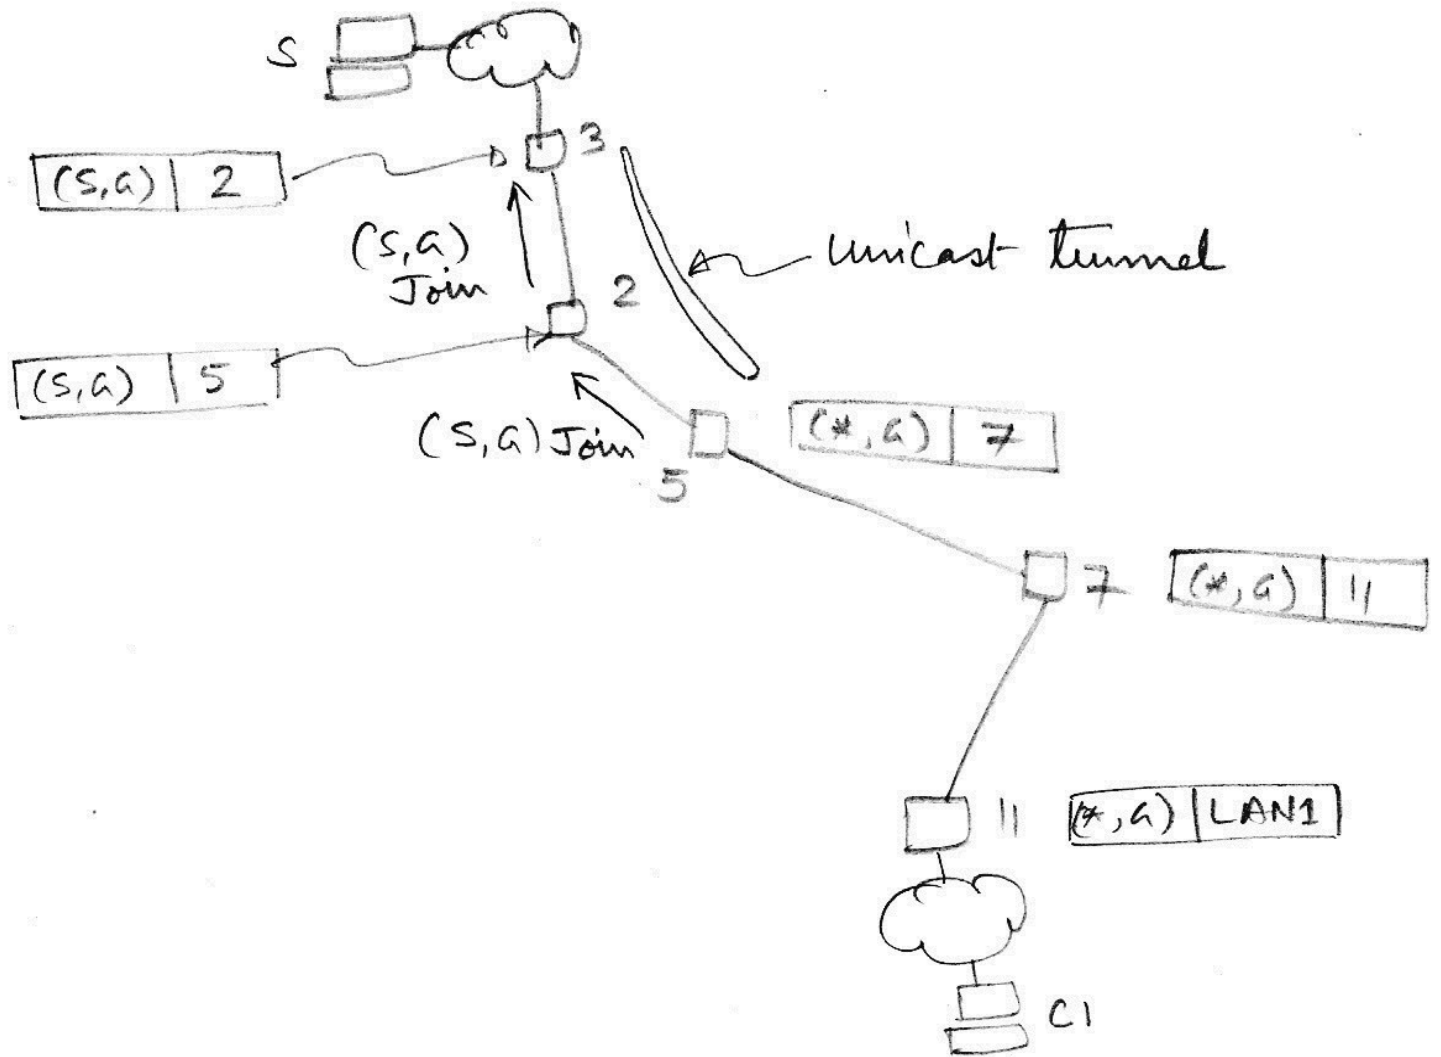

# Register packets

- The source for multicast packets gives packets to its designated router
- The DR encapsulates the multicast packets in unicast packets
  - Protocol field for unicast IP packets is set to IP (IP in IP tunneling)
- The encapsulated packets sent to RP

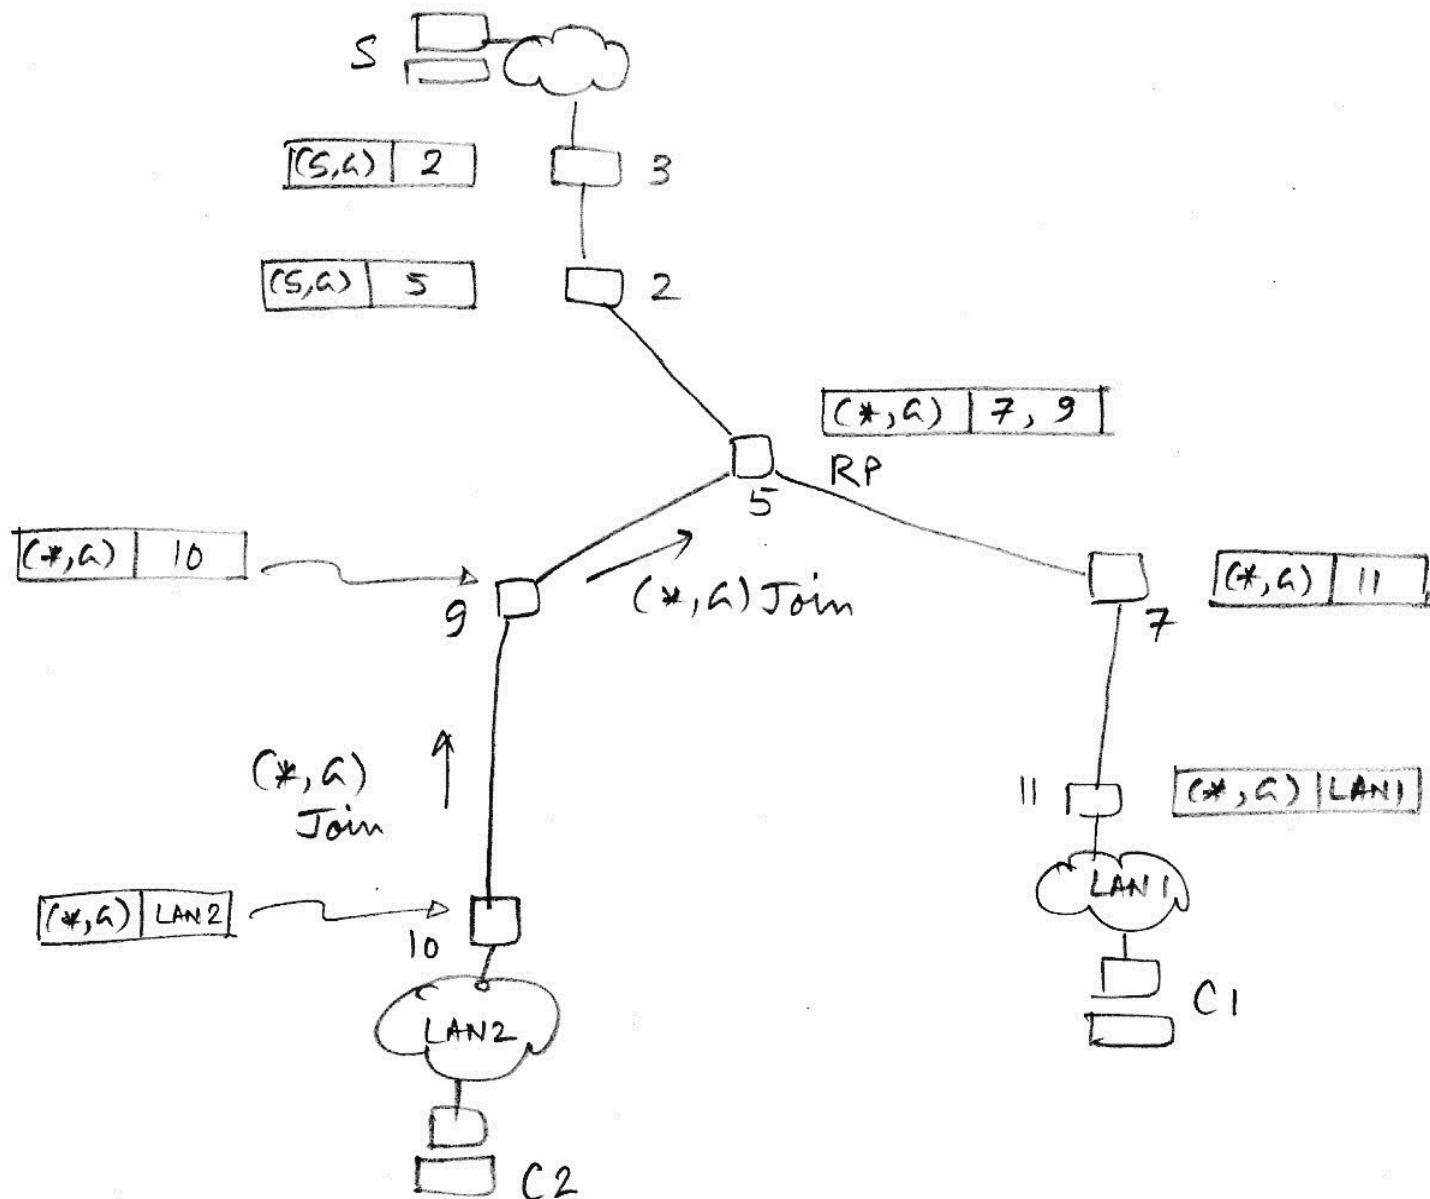

# What RP does?

- RP de-encapsulates the packets.
- Forwards them to nodes as per multicast forwarding table
- RP initiates (S,G) join towards S (Phase-II: Register Stop)

- When RP starts getting two copies of multicast packets
  - Discards the encapsulated packets
  - Send register stop message to DR of S

# Routing rules

- Node have (S,G) children  $C1 = \{A, B, C\}$
- Node also have (\*,G) children as  $C2 = \{B, D, E, S\}$ , (S,G,rpt) children as  $C3$
- If a packet received from shortest path to S
  - Packet forwarded to  $((C1 \cup C2) - \{S\}) - C3$

- If packet received from shortest path to RP, but not from shortest path to S
  - Forwarded to  $C2-C3$

# Phase -III : Shorest path tree

---

- Any router can optionally decide to send (S,G) join towards S
- (S,G) join reaches to some router already having (S,G) state, or to S
- The router receives two copies of each packet

- Router sends  $(S, G, rpt)$  prune towards RP
- The prune forwarded till it reaches a router which have at least one child having  $(*, G)$  but no  $(S, G, rpt)$  state

# How RP is selected?

- Some of the routers in the network - configured to be candidates for being RP
- A Bootstrap Router through a simple election process
- Each candidate tells the BSR of its willingness to be RP
- BSR builds a RP-set and broadcast it periodically to all the nodes in network

- Every node uses hashing on group address to determine the RP for that group from the RP-set.
- There can be more than one RP
- Each group will have only one RP
